University of Wisconsin-Madison

Abstract

An assessment is made of the effects of tension gradients on the free vibrations of tethers. A perturbation procedure is developed in general terms. Specific cases considered include centrifugal loading and distributions from gravity gradients. Results indicate that such gradients can significantly alter natural frequencies, with changes nearly independent of wave number. Distortions in mode shapes also occur, but are less severe. Node points and maximum amplitudes are shifted in the direction of decreasing tension.

Equations of motion are presented for flow-induced vibrations in tethers used for fluid transfer, such as propellants and coolants. Response curves are obtained by numerical integration. It has been found that if the flow has a pulsating characteristic, large amplitude displacements are likely to develop over a wide range of system parameters.

I. Introduction

Mechanical vibrations can naturally occur in tether systems designed for a variety of applications. One of the most important influences on vibrations of such flexible members is internal tension, which may change considerably because of large unsupported lengths. An objective of this work is to determine the effects of tension gradients on free vibrations. This is a necessary prerequisite for forced vibration analysis by modal procedures.

Tethers may also function as fluid lines for the transfer of propellants, contaminated liquids, coolants, etc. It is important to be able to determine the dynamic response and identify the influence of factors such as fluid velocity, fluctuating flow, tether stiffness and effective tension. These issues are considered in the work which follows.

II. Tension Gradient Effects on the Free Vibrations of Tethers

For basic problems in which the tension T and mass per unit length ρ are functions of the axial coordinate, x, the equation of motion for the transverse displacement component v is

\[
\frac{\partial}{\partial x} \left[ T(x) \frac{\partial v}{\partial x} \right] = \rho(x) \left[ \frac{\partial^2 v}{\partial t^2} - \omega_n^2 v \right] \tag{1}
\]

where t and ω denote time and tether rotational speed, respectively. For small axial gradients, the following substitutions are made for T and ρ:

\[
T(x) = T_0 [1 + \delta(x)] \tag{2}
\]

\[
\rho(x) = \rho_0 [1 + \epsilon(x)] \tag{3}
\]

The form of the solution used for a typical modal component can be expressed as

\[
v_n(x,t) = [V_n(x) + \sum_m a_{mn} V_m(x)] \exp(i \omega_n t) \tag{4}
\]

\[
\omega_n^* = \omega_n (1 + b_n) \tag{5}
\]

Here \(V_n(x)\) and \(\omega_n^*\) are solutions to the gradient-free problem, i.e.,

\[
V_n(x) = \sin \frac{n \pi x}{L} \quad n = 1, 2, ...
\]

\[
\omega_n^* = \frac{M_e (\alpha n \pi)^2}{\rho_0 L} - \omega_n^2 \tag{6}
\]

where \(M_e\) represents a concentrated end mass. The coefficients \(a_m\) and \(b_n\) are small order terms and facilitate the development of the perturbation solution. These expressions are now substituted into the equation of motion, (1):

\[
[T_0 V_n^\prime + \rho_o \omega_n^2 V_n + \rho_o \omega_n^2 V_n] + T_0 [\delta(x)V_n^\prime]^\prime
\]

\[
+ \rho_o \omega_n^2 [(1 + \alpha^2/\omega_n^2)\epsilon(x) + b_n]V_n
\]

\[
+ \sum_m a_{mn} [T_0 V_m^\prime + \rho_o \omega_n^2 (1 + \alpha^2/\omega_n^2)V_m]
\]

\[
= -\rho_o \omega_n^2 \epsilon(x)b_n V_n - T_0 \sum_m [\delta(x)a_m V_m^\prime]^\prime \tag{8}
\]

\[
-\rho_o \omega_n^2 \sum_m a_m [b_n + b_n \epsilon(x) + \epsilon(x) + \epsilon(x)\alpha^2/\omega_n^2].
\]

The equation for first order perturbation terms is obtained by deleting the right side of (8):

\[
T_0 [\delta(x)V_n^\prime]^\prime + \rho_o \omega_n^2 [(1 + \alpha^2/\omega_n^2)\epsilon(x) + b_n]V_n
\]

\[
+ \sum_m a_{mn} [T_0 V_m^\prime + \rho_o \omega_n^2 (1 + \alpha^2/\omega_n^2)V_m^\prime] = 0. \tag{9}
\]

Series coefficients \(a_m\) and \(b_n\) can be determined from the following expressions:

\[
a_m = [T_0 \int_0^L [\delta(x)\epsilon(x)] V_mdx
\]

\[
+ \rho_o \omega_n^2 (1 + \alpha^2/\omega_n^2) \int_0^L \epsilon(x) V_m V_n dx]/
\]

\[
k_m \rho_o \omega_n^2 (1 + \alpha^2/\omega_n^2)(\epsilon^2 - \omega_n^2) \tag{10a}
\]

*Member AIAA
\[ b_n = \left[ -T_0/\rho_n^2 \omega_n^2 \left( 1 + \omega^2/\omega_n^2 \right) \right] / \int_0^L \left[ s(x) \right] V_n(x) \] 
\[ - (1/k_n) \int_0^L V_n^2 \epsilon(x) dx \]  
\text{(10b)}

where

\[ V_m^2(x) = -\omega^2 \left( 1 + \omega^2/\omega_n^2 \right) V_m(x) \rho_n/T_0 \]  
\text{(11)}

\[ k_m = \int_0^L V_m^2(x) \, dx \]  
\text{(12)}

**Centrifugal Tension Gradient**

Consider an idealized example in which the axial gradient results from rotation only. The origin of coordinates is at the center of rotation, the length is \( L \) and an end mass \( M_E \) has negligible relative displacement (as in some simple constellations). The mass per unit length is also constant. Thus

\[ c(x) = 0 \]

\[ T(x) = T_0 \left[ 1 + \epsilon(x) \right] \]

\[ = M_E \epsilon \omega^2 \left[ 1 + \rho_0 \epsilon^2 - x^2/2M_E \epsilon \right] . \]  
\text{(13)}

The perturbation parameters follow from (10):

\[ a_m = 2M_T (-1)^{m+n}mn(m^2+n^2)/ \]

\[ (1+\omega^2/\omega_n^2)M_E \pi n^2(m+n)^2(m-n)^2(m^2-n^2)^2 \]  
\text{(14)}

\[ b_n = (M_T/2M_E)(1-3/4n^2\pi^2) \]  
\text{(15)}

where \( M_T \) is the tether mass. From (15), the frequency change will be nearly the same for all modes. The percentage difference can be substantial, as shown in Fig. 1. Modifications in mode shapes are not as large. From Figs. 2-4, it can be seen that maximum amplitudes and node points are shifted in the direction of decreasing tension.

**Gravity Gradient Tension Distribution**

In this example, the model consists of a tether aligned with the local vertical having a lower end mass \( M_1 \) at \( r_1 \) and an upper end mass \( M_2 \) at \( r_2 \). Force equilibrium for the system requires

\[ \omega^2 \left[ M_2r_2 + M_1r_1 + M_T(r_2 + r_1)/2 \right] \]

\[ = GM \left[ M_1/r_1^2 + M_2/r_2^2 + M_T/r_1r_2 \right] \]  
\text{(16)}

where \( GM \) is the gravitational constant of the earth. At a generic position \( r \), the internal tether tension is
Fig. 4 Third Mode of Rotating Tether With Added Mass.

\[ T(r) = \frac{\omega^2 M}{4 \pi} (r_1^2 - r^2) + \frac{G M M_1}{r_1} (1 - 1/r) \phi + F_1 \]  (17)

where \( F_1 \) is the force difference acting on \( M_1 \).

\[ F_1 = \frac{G M M_1}{r_1^2} - M_1 \phi \]  (18)

The modification in mode shapes and frequencies will have the same form as given in (4) and (5). However, the axial coordinate \( x \) will originate at mass \( M_1 \), i.e.,

\[ x = r - r_1. \]  (19)

Frequency correction coefficients depend upon all system parameters:

\[ b_n = \frac{\left( \frac{M}{2M_1} \right)}{1 - \frac{r_1^2 \phi}{2 \pi}} \left[ 1 - \frac{(\phi r_1^2)}{r_1^2 (2/3 + 1/n^2 \pi^2)} \right] \]

\[ + \frac{(\phi r_1^2)}{2 \pi} \left[ 1 - \frac{(\phi r_1^2)}{r_1^2 (2/3 + 1/2 n^2 \pi^2)} \right]. \]  (20)

For cases in which \( \phi r_1^2 \) is small, this can be simplified:

\[ b_n = \left( \frac{M}{2M_1} \right) \left[ 1 - \frac{(\phi r_1^2)}{r_1^2 (2/3 + 1/n^2 \pi^2)} \right] \]

\[ + \frac{(\phi r_1^2)}{2 \pi} \left[ 1 - \frac{(\phi r_1^2)}{r_1^2 (2/3 + 3/n^2 \pi^2)} \right]. \]  (21)

It can be seen that the modification to the square of each natural frequency is essentially the same, i.e., one half of the ratio of tether mass to end mass. Numerical results are presented in Table 1.

Similarly the amplitude coefficients are obtained from (10a), i.e.,

\[ a_m = 2\pi l / (m^2 - n^2)(1 + \phi^2/\omega_n^2) \]

where

\[ I = \int_0^l [\varphi(x) \varphi(x')] V_2(x') \, dx \]

\[ = \left( \frac{G M M_1}{r_1} r_1^2 \right) M_1 \phi_{1n} \eta \right] ((n+m)^2 + (n-m)^2)^{-1} \]

\[ + \left( \frac{2 G M M_1}{r_1} \right)^3 + \left( \frac{M_1}{r_1} \right)^2 \eta \right] ((n-m)^2)^{-1} \]

\[ \times \left( (n-m)^2 + (n+m)^2 \right) \left( (n-m)^2 - 2 \right) (n-m)^2 + 2 \]

\[ (n+m)^2 \left( (n-m)^2 - 2 \right) (n+m)^2 + 2 \]  (22)

As with the preceding example, moderate distortion of the mode shapes will result for a wide range of numerical values of the parameters in (22).

### III. Flow-Induced Vibrations

The model used consists of a completely flexible uniform tether of length \( \xi \), cross-sectional area \( A_T \) and mass per unit length \( \rho_T \). The fluid velocity is \( c_T \), cross-sectional flow area \( A_T \) and mass per unit length \( \rho_T \). Gravity gradient and rotational effects are not included in the model. It is also assumed that nominal tube dimensions do not significantly change with pressurization and motion. The fluid is considered viscous and incompressible.

The undeformed centerline of the tether coincides with the \( x \) axis. Free and forced response of the tether is allowed in both the \( x-y \) and \( x-z \) planes along with longitudinal deformations. An effective axial force \( F_{\text{EFF}} \) includes the induced axial load from internal pressure. Nonlinear tension effects are accounted for by including higher order terms in the tether extension expression.

Equations of motion were developed using Hamilton's principle and general variational calculus procedures. These equations follow for the axial, transverse and lateral directions:

*This group of terms is zero if \( m \) and \( n \) are both odd or both even.
Thus the corresponding equation of motion is

\[ v_r + \frac{2 \rho F c}{c_r (\rho F + \rho \tau)} \sum_{n=1}^{n-2} \frac{2n^2}{r^2 - r^2} \frac{v_r}{r} \]

\[ + \frac{\tau_0 \rho \tau}{c_r (\rho F + \rho \tau)} \sum_{n=1}^{n-2} \frac{2n^2}{r^2 - r^2} \frac{v_r}{r} \]

\[ + \frac{(T_{EFF} - \rho F^2 \pi^2 r^2)}{4z^4 (\rho F + \rho \tau)} \sum_{n=1}^{n-2} \frac{2n^2}{r^2 - r^2} \frac{v_r}{r} \]

\[- \frac{2n^2}{r^2 - r^2} \frac{v_r}{r} = 0 \]

where \((r/n)\) is odd, otherwise the two series in (27) are zero. The fluid velocity is denoted by \(c_r\). In the case of flow with a pulsating component, the representation is

\[ c_r = c_0 (1 + \mu \cos \lambda t) \]

For numerical purposes, dimensionless variables are defined as follows:

\[ \tilde{v} = v/x, \quad \tilde{w} = w/x, \quad \tilde{\xi} = \omega t, \quad \tilde{v}_r = \omega_t \]

\[ \tilde{v}_r = (T_{EFF} - \rho F c^2 \pi^2 r^2)/(\rho F + \rho \tau) \]

### Computational Results

Tether dynamic response for multiple modes was determined by a Runge-Kutta integration routine. Approximately 6000 time steps per cycle were used. For both examples the harmonic coefficient \((\mu)\) was 0.40, damping was 1% and the length was 100 m. In the first case, shown in Fig. 5, a fluid velocity of 1 m/s is low enough that steady state motion characterizes the response. However, as seen from Fig. 6, an increase in m/s causes an unstable response with midspan displacements growing exponentially. Generally the nature of the time histories is quite sensitive to changes in system parameters.

### IV. CONCLUSIONS

A perturbation procedure has been outlined for use in the vibration analysis of tethers having mass or tension gradients. When applied to the cases of tension variations from rotation or gravity gradients, it has been shown that vibration frequencies can be significantly changed. Asymmetries occur in mode shapes characterized by shifts in locations of maximum values and node points toward low tension regions. Equations of motion have also been developed for flow-induced vibrations of tethers. Results indicate that if the velocity has a harmonic variation, large amplitude motion is possible over a wide range of physical parameters.
