Dry-Wall Target Chambers for Direct-Drive Laser Fusion

Gerald L. Kulcinski and Robert R. Peterson

presenting for the staff of the
Fusion Technology Institute
University of Wisconsin-Madison

US-Japan Workshop on Laser Fusion
January 25-27, 2001
Lawrence Livermore National Laboratory
Objective of Present Study

• To understand if the recent NRL direct drive target design can survive in a SOMBRERO-type dry wall chamber (no vaporization of C-C composite)

• To investigate the degree to which the Xe fill gas could be reduced to lower the aerodynamic frictional heating of direct drive targets.

• Apply latest analysis methods and explore the possibility of innovative injection techniques in dry wall chambers
Roadmap to Calculate IFE Wall/Target Survival Conditions

1. **Target Output**
   - NRL Sombrero

2. **Gas Protection**
   - Gas Species
   - Gas Density
   - Radius
   - Twall

3. **First Wall T(t)**
   - Vaporization?
     - no
     - yes

4. **Opacity**
   - EOSOPA IONMIX

5. **Material**

6. **First Wall Vaporization?**
   - no
   - yes

7. **Friction**
   - \( \sigma T^4 \)

8. **Velocity**
   - ANSYS
     - yes
     - no

9. **Target Injection**
   - Distance in Chamber
   - Tube
   - Straight

10. **\( \Delta T > 1.5 \text{ K?} \)**
    - yes
    - no

11. **Chamber Works!**
First Wall Erosion and Target Heating During Injection are Competing Concerns in Direct-Drive Laser Fusion Dry-Wall Target Chambers

Chamber Physics Critical Issues Involve Target Output, Gas Behavior and First Wall Response

UW uses the BUCKY 1-D Radiation-Hydrodynamics Code to Simulate Target, Gas Behavior and Wall Response.
BUCKY, a Flexible 1-D Lagrangian Radiation-Hydrodynamics Code; Useful in Predicting Target Output and Target Chamber Dynamics

- 1-D Lagrangian MHD (spherical, cylindrical or slab).
- Thermal conduction with diffusion.
- Applied electrical current with magnetic field and pressure calculation.
- Equilibrium electrical conductivities
- Radiation transport with multi-group flux-limited diffusion, method of short characteristics, and variable Eddington.
- Non-LTE CRE line transport.
- Opacities and equations of state from EOSOPA or SESAME.
BUCKY, a Flexible 1-D Lagrangian Radiation-Hydrodynamics Code; Useful in Predicting Target Output and Target Chamber Dynamics

- Thermonuclear burn (DT, DD, DHe³) with in-flight reactions.
- Fusion product transport; time-dependent charged particle tracking, neutron energy deposition.

- Applied energy sources: time and energy dependent ions, electrons, x-rays and lasers (normal incidence only).
- Moderate energy density physics: melting, vaporization, and thermal conduction in solids and liquids.

- Benchmarking: x-ray burn-through and shock experiments on Nova and Omega, x-ray vaporization, RHEPP melting and vaporization, PBFA-II K_α emission, …
- Platforms: UNIX, PC, MAC
Direct-Drive Targets Under Consideration Have Different Output

Direct-drive Laser Targets

**SOMBRERO (1990)**
Standard Direct-Drive

**NRL (1999)**
Radiation Tailored-Wetted Foam

**NRL (1999)**
Wetted Foam

---

**Debris Ions**
- 94 keV D - 5.81 MJ
- 141 keV T - 8.72 MJ
- 138 keV H - 9.24 MJ
- 188 keV He - 4.49 MJ
- 1600 keV C - 55.24 MJ
- Total - 83.24 MJ per shot

---

**Laser Energy: 4 MJ**
- Laser Type: KrF
- Gain: 100
- Yield: 400 MJ

**Laser Energy: 1.3 MJ**
- Laser Type: KrF
- Gain: 127
- Yield: 165 MJ

**Laser Energy: 1.6 MJ**
- Laser Type: KrF
- Gain: 108
- Yield: 173 MJ

**Spectra:**
- Calculated with BUCKY
- Calculated by NRL
- Calculated with Lasnex

**Spectra:**
- Not Yet Calculated
Laser Quickly Burns though 300 Å Au and 1 μ Plastic and Launches a Shock in DT-wetted Foam

- Close-up of laser burning through thin gold and plastic shells of NRL target
- Gold and plastic are hot and rapidly rarifying, probably not in local thermodynamic equilibrium.
- Gold is expanding at 75 km/s from laser blow-off.
- 22% of DT ice is burned; NRL and LLNL get about 32%, though peak $\rho R$ (LLNL) and bang time (NRL) do agree.
- Very little DT in wetted foam is burned.
- This calculation yielded 115 MJ; another, 200 MJ
- Other yields would be achieved with further tuning.
- Target expands at a few time $10^8$ cm/s and radiates.
The particle energy of each species in each zone is then calculated as $mv^2/2$ on the final time step of the BUCKY run. This time is late enough that the ion energies are unchanging. The numbers of ions of each species in each zone are plotted against ion energy.

The spectra from direct fusion product D, T, H, He$^3$, and He$^4$ are calculated by BUCKY but they don’t make it out of the target.

The ion spectra is more energetic for 200 MJ yield.
Ion Spectrum Experiments on Z are in Progress to Validate Target Output Calculations

- CR39 film measures ion energy through damage track lengths.
- Open collimator LOS 1/2 8” from Z
- Z-pincha x-ray source
- Ion track analysis and supporting BUCKY simulations are in progress.
- Pin Hole Camera 10 degrees tilt to center. 9” from center of camera hole plate to blast shield.

SHOT # 603 06/26/00 16:13
X-ray Spectra from Targets is Changed by High Z Components and Yield

• X-ray spectra are converted to sums of 3 black-body spectra.
• Time-dependant spectra are in Gaussian pulses with 1 ns half-widths and are used in chamber simulations.
• Time-integrated fluences are shown for 115 MJ and 200 MJ NRL and 400 MJ SOMBRERO.
• The presence of Au in the NRL targets adds emission in spectral region above a few keV.
• At higher yield the Au is more important.
The threat spectrum can be thought of as arising from three contributions: fast x-rays, unstopped ions, and re-radiated x-rays.

Some debris ions are deposited in chamber gas, which re-radiates the energy in the form of soft x-rays.

The x-rays directly released by the target are, for Xe at the pressures contemplated for the DD target, almost all absorbed by the wall.

The wall (or armor) reacts to these insults in a manner largely determined by its thermal conductivity and stopping power.
For the current calculations, IONMIX has been used to generate Non-LTE Xe opacity tables.

- Xe gas at or below 0.5 Torr in density is not in LTE.
- Non-LTE (IONMIX) ionization is substantially below the LTE (Saha) ionization.
- The Xe opacity can differ substantially between LTE (EOSOPC) and Non-LTE (IONMIX).
- IONMIX opacities are used in this study.
A C-C Target Chamber Can Survive, with Proper Gas Protection and Wall Temperature

- A series of BUCKY calculations have been performed of the response of a 6.5 m radius graphite wall to the explosions of SOMBRERO and NRL targets. Time-of-flight dispersion of debris ions is important, especially for low gas density.

- The gas density and equilibrium wall temperature have been varied to find the highest wall temperature that avoids vaporization at a given gas density.

- Vaporization is defined as more than one mono-layer of mass loss from the surface per shot.

- The use of Xe gas to absorb and re-emit target energy increases the allowable wall temperature substantially.
For example, the first wall does not vaporize for the SOMBRERO target in a 6.5m radius chamber filled with 0.1 torr Xe and a wall equilibrium temperature of 1450°C.

- The separation in time of the insults from the prompt x-ray, the ions, and the re-radiated x-rays is crucial to the survival of the wall.
- The Xe serves to absorb the vast majority of the ion energy and almost half of the prompt x-rays and slowly re-radiates the absorbed energy at a rate determined by the Plank emission opacity of the Xe.
First Wall Erosion and Target Heating During Injection are Competing Concerns in Direct-Drive Laser Fusion Dry-Wall Target Chambers
Target Injection for Laser Fusion Chambers

Assumptions For NRL Target Heating Calculations

- Injection velocity = 400 m/s
- Target spectral reflectivity = 99%
- Transport distance in chamber = 2 m (tube)
- Thermal diffusivity of CH @ 18 K = 0.009 cm²/s
- ΔT at DT/CH interface < 1.5 K
- Tumbling target (symmetric heat transfer)
The Heat Flux Absorbed in the Outer Surface of the Target Depends on the FW Temperature and the Target Emissivity.
The Heat Flux Due to Aerodynamic Friction on the Target Outer Shell is Strongly Dependant on the Chamber Gas Temperature, its Pressure and the Velocity of the Target.

Frictional Heat Flux for a 6 mm Diameter Target

Frictional Heat Flux for a 4 mm Diameter Target
The Target Injection Tube Protects the Target from Thermal Damage During Injection

- A target injection tube extends from the top of the chamber to within 2 meters of the chamber center.
- It consists of a tungsten core which is He gas cooled in a closed cycle cooling system.
- The tungsten core is surrounded by a carbon double tube assembly cooled by Xe gas, extending 0.5m beyond the tungsten core.
- The Xe gas after cooling the carbon tube enters the chamber replenishing the chamber buffer gas.
- The tungsten core is stationary, but, the carbon tube is slowly moved forward at the rate at which the carbon evaporates.
- The target is shielded from high temperature radiation from the first wall, and by tube differential pumping avoids frictional heating with the buffer gas along most of its trajectory.
